A Study of L2 Spoken Corpora: The Gap between Productive Skills of Japanese EFL Learners and the Corpus-Based ELT Textbooks

Aika Miura
Toyko Keizai University

Abstract
This study aims to observe the gap between productive skills of particular pragmatic features of Japanese EFL learners and the expectations and decisions the authors of corpus-based ELT textbook series make regarding the types of language to include. So-called “conversational strategies” in the Touchstone Series from Cambridge University Press with corpus-based syllabus design are examined in the NICT JLE Corpus, which contains more than one million words of 1,200 Japanese EFL learners with nine different proficiency levels. The research suggests that Japanese learners do not necessarily exhibit their productive skills as the way the textbook series presents target language and strategies. The learners at various proficiency levels performed relatively differently from each other. The intermediate learners tended to overuse particular words and phrases compared to those who were at upper intermediate and advanced proficiency levels. Research into the NICT JLE Corpus suggests a transitional nature of L2 development which is particular to Japanese EFL learners, and the results can be used to complement ELT textbooks and improve language instruction in Japan, specifically at the tertiary level.

Aika Miura currently teaches at Tokyo Keizai University, Toho University and Tokyo University of Science. She holds a B.A. (Linguistics) from Reading University and an M.A. (Language Studies) from Lancaster University in the UK. Her interests include second language acquisition and corpus linguistics. She can be contacted at dawn1110am@yahoo.co.jp.

SLA and Learner Corpora

In order to be an effective language teacher, it is advantageous to have considerable background regarding the study of second language acquisition as well as pedagogy related to L2 learners. In support of this Ellis (1994) states, “The study of SLA provides a body of knowledge which teachers can use to evaluate their own pedagogic practices” (p. 4). There have been a great number of different approaches to describe learner language. Ellis (1994) identified four major approaches; the study of learners’ errors, the study of developmental patterns, the study of variability, and the study of pragmatic features. The description of learner language enables language teachers to improve syllabus design, material design, task design and testing (Tono, 2000). Thus, when describing the study of developmental patterns, Ellis (1994) highlighted the importance of “unplanned language use” which is found in naturalistic settings (p. 82). This term corresponds to what Ellis (1994) called “natural language use,” which “occurs in the course of using the L2 in the kind of communication that learners engage in when they are not being studied” (p. 672).

Generally, the focus of the SLA researcher is to collect data that reflect learners’ attempts to use the L2 in either comprehension or production. However, Granger (2002) pointed out that much current SLA “tends to be dismissive of natural language use data” for it is
difficult to control the variables that affect learner output in a non-experimental context, and to subject a large number of informants to experimentation (p. 5-6). Therefore, questions have been raised whether the results of the studies on a small number of samples of learner data can be generalized.

Recently, researchers using computer based technologies are able to collect and store a large amount of learner data, and to analyze it automatically or semi-automatically using currently available linguistic software and tools (Granger, 2002). This advancement makes it possible to produce research results from a larger number of participants than previously possible, which leads to higher validity and reliability regarding statistical data. Therefore, situational specific data can be expanded and researchers can afford to make more generalized conclusions regarding the results. Granger (2002) refers to this large amount of learner data as “computer learner corpora” (CLC)(p. 4).

The research on CLC stems from recent advances in the field of corpus linguistics, specifically within the past decade CLC has had an extensive influence on language teaching regarding both second language acquisition as well as pedagogy (Granger, 2002; Ishikawa, 2008). Learner corpora of various kinds such as speakers of different mother tongues, proficiency levels, age, modes (spoken or written), and registers (academic or non-academic) have been developed and improved on. As for Japanese EFL learners and language researchers, learner corpora are available online, such as the Japanese English as a Foreign Language Learner (JEFL) Corpus (Tono, 2007) and the Nagoya Interlanguage Corpus of English (NICE) (Sugiura, 2009). Web sites that support learner corpora data have unarguably supplied researchers and language teachers with an abundance of learner data that can be used for studies ranging from the smaller and more situational-specific classroom action research types to larger scale studies.

Access to a corpus enables researchers to investigate the learners’ errors, developmental patterns, variability and pragmatic features.
Hunston (2002) further commented that “corpora lead to new descriptions of a language, so that the content of what the language teacher is teaching, is perceived to change in radical ways” (p. 137). Granger (2002) also suggested that “teachers and researchers often have useful intuitions about what does or does not constitute an area of difficulty for learners, but this intuition needs to be borne out by empirical data from learner corpora” (p. 23).

**Corpora and its Application to ELT**

Based on the literature, corpora can be defined as a principled collection of texts, written or spoken, stored on a computer (Biber, Conrad, & Reppen, 1998; Granger, 2002; McCarthy, 2004; O’Keefe, McCarthy, & Carter, 2007). From this, researchers can study naturally occurring language use. According to Granger (2002), studies on corpora specifically highlight a quantitative approach as researchers are able to discern what is most likely to occur in language, or “frequency”, which rules out the intuitive awareness factor in the collection of data and the preceding analysis of it. In this way, corpus linguistics has contributed to a number of areas in language pedagogy including syllabus design and materials development (Granger, 2002; Hunston, 2002; Reppen & Simpson, 2002; McEnery, Xiao, & Tono, 2006).

Kennedy (1998) summarizes the importance of syllabus and materials design by stating corpora supply “information on the distribution of the elements and processes of a language”, and “it can influence the content of language teaching by affecting selection of what to teach, the sequencing of pedagogy, and the weight given to items or parts of the language being taught, thus contributing directly to the content of instructions” (p. 281). After comparing “internationally successful coursebooks” to the Cambridge and Nottingham Corpus of Discourse in English (CANCODE), Carter (1998) discovered that
dialogues taken from selected non-corpus-based textbooks lacked core spoken language features such as discourse markers, vague language, ellipsis and hedges.

**Native vs. Non-Native Corpora**

Several studies (Cook, 1998; Widdowson, 2000) have leveled criticisms against a corpus-based approach which tends to heavily rely on the aspect of “frequency” and “authenticity” when applied to language teaching (Hunston, 2002; Tono, 2008). Cook (1998) argued that “even within the native-speaker community it is often the infrequent word or expression which is most powerful and most communicatively effective” (p. 6). Therefore, “frequency information obtained from native-speaker corpora alone is not sufficient to inform curriculum and material design” (McEnery et al., 2006, p. 101).

In this respect, the research into CLC plays an important role in applying the data from corpora studies to language pedagogy (McEnery et al., 2006; O’Keeffe et al., 2007). Native corpora “give no indication whatsoever of the difficulty they present for learners in general or for a specific category of learners” (Granger, 2002, p. 21). The NS (native speakers) / NNS (non-native speakers) comparison enables us to notice gaps between learners’ interlanguage and the language they are learning (McEnery et al., 2006) This is apparent in NNS learners’ “overuse” and “underuse” of selected items, as well as “NL (native language) transfer” and “avoidance strategies”, when compared to the NS corpora (Granger, 2002; Leech, 1998). As for objections to this type of comparison regarding the placing the importance on the native “norm” in language teaching see Widdowson (2000), Cook (1998), Granger (2002,), and Hunston (2002).

**Corpora and Textbook Authoring**

Apart from the aforementioned controversial issues related to the use of corpora in language teaching, material development and syllabus
design continue to be based on corpora. The importance of corpora is evident in the compilation of learners’ dictionaries, which are now based on continually updated multi-million word databases of language, such as the Longman Corpus and the Cambridge International Corpus (O’Keeffe et al., 2007; Tono, Izumi, & Kaneko, 2005). Aside from the recent development of corpus based dictionaries, text book authors and publishers are also utilizing corpora in material development.

The Touchstone Series is one of the more recently published ELT textbooks whose dialogues and entire syllabi are informed by corpus data (McCarthy, 2004; McCarthy, McCarten, & Sandiford, 2005a, 2005b, 2005c; McCarthy et al., 2006a, 2006b; O’Keefe et al., 2007). The series is “based on the most common words and phrases in the North American segment of Cambridge International Corpus (CIC)” which contains 700 million words of text (O’Keefe et al., 2007, p.22). According to McCarthy (2004), the authors interpret and mediate their corpus research by looking at word lists from the Corpus and searching for the most frequent and typical uses in everyday conversation. Then they decide which words are the most important ones to be included, considering whether they suit the interests of learners and are most relevant to their lives or not. For pedagogical considerations, it should be noted that “corpus data alone does not dictate an instructional syllabus” (McCarthy, 2004, p. 15), since high-frequency language is not always appropriate for beginners to start to learn (Ishikawa, 2008; McEnery et al., 2006; Tono, 2008).

**Learner Corpus Data and its Proficiency Levels**

The National Institute of Information and Communication Technology (NICT) developed the NICT JLE Corpus, a learner corpus of Japanese Learners of English (JLE), which contains more than one million words from approximately 1,200 Japanese subjects’ 15-minute interviews (Izumi, Uchimoto, & Isahara, 2004). The data collected from
the interviews comes from the Standard Speaking Test (SST) created by ALC Press. The SST is based on the Oral Proficiency Interview of the American Council on the Teaching of Foreign Languages. Table 1 shows the distribution of subjects’ proficiency levels, types (the total number of different word forms in each level), and tokens (the total occurrences of any given word forms in each level). Those who fall into levels 1 to 3 can be described as novice learners and those who fit levels 4 to 8 are considered intermediate ones, and finally, test takers with the highest scores are classified as the most advanced at Level 9 (see Izumi et al., 2004).

Conversational Strategies and the Touchstone Series

The primary aim of this study is to investigate the Japanese learners’ use of pragmatic features based on the detailed analyses of the native speakers’ corpus. This should be distinguished from research into “discourse markers” based on pragmatic theories and “formulaic expressions” (De Cock, Granger, Leech, & McEnery, 1998; Fraser, 1993).

O’Keeffe et al. (2007) and McCarthy (2008) defined conversational strategies as chunks, which are automatically extracted multi-word strings from the corpus that display pragmatic functions such as hedging, vagueness, and discourse marking, the preservation of face and the expression of politeness, rather than belonging to syntactic and semantic categories (McCarthy & Carter, 2006; O’Keeffe et al., 2007). The presence or absence of common chunks has been considered a
useful measure of comparison and evaluation of learner competence compared to native speaker competence (McCarthy & Carter, 2006; O’Keeffe et al., 2007). De Cock et al. (1998) offer their definition of chunks as “formulaic expressions, i.e. frequently used multi-word units that perform pragmatic or discourse structuring functions” (De Cock et al., 1998, pp. 68-69).

The *Touchstone Series* is composed of *Book 1* for beginners, *Book 2* for high beginners, *Book 3* for low-intermediate, and *Book 4* for intermediate learners. Each book consists of 12 units, which includes a section devoted to conversational strategies presented in a dialogue followed by grammatical explanations, language practice exercises and listening comprehension quizzes. The following sample dialogue is taken from *Touchstone Book 2* (McCarthy et al., 2005b, p. 71) and focuses on the target language form "I guess, which is used “when you’re not 100% sure about something, or if you don’t want to sound 100% sure”:

Chris: You know, we should take a few days off sometime.
Adam: Yeah, we should. Definitely.
Chris: We could go to Mexico or something.
Adam: That’s a great idea.
Chris: We could even go for couple of weeks.
Adam: Well, maybe. *I guess* we could, but…
Chris: You know, we could just quit our jobs and maybe go backpacking for a few months…..
Adam: Well, I don’t know. I’d like to, but….. I guess I need to keep this job, you know, to pay for school and stuff.
Chris: Yeah, me too, *I guess*.

In the data analysis, the list of conversational strategies was initially made from four books of the series (totaling 81 items). The functions of the strategies are defined in each book, including the inclusion of corpus-based information, i.e., “I guess is one of the top 20 expressions
Miura, “L2 Spoken Corpora”

in conversation” (McCarthy et al., 2005b, p. 71). Table 2 shows the items which are specifically discussed in the paper.

| (5) just* | 4 | 6 | (p. 58-9) | Making your meaning clearer | “Like” is one of the top 15 words. It is about 6 times more frequent in conversation than in writing. |
| (6) like | 4 | 8 | (p. 81) | Various functions (See the results and discussion section.) |
| (7) so | 4 | 4 | (p. 39) | Various functions (See the results and discussion section.) | Checking your understanding |

Note: Empty cells signify corpus information was not provided regarding target language in the table. The use of items marked by (*) is further discussed in the results section.

The principle data regarding the occurrence of each item was searched utilizing the NICT JLE Corpus. Figure 1 shows an extract of 10 concordance lines for I guess in a sub-corpus of Level 8 from the NICT JLE Corpus. It should be noted that most types of corpora generally have somewhat of an original annotation scheme, which is also true in the case of the NICT JLE Corpus as #F# means filler or filled pause, #SC# means self correction, “R” means repetition and last #JP# means Japanese (see Izumi et al., 2004).
Results

The distribution of *I mean* and *I guess* in the NICT JLE Corpus is shown in Figure 2. Since tokens in each proficiency level were different as indicated in Table 1, the frequency of analyzed words or phrases was normalized at 100,000 word tokens. A sample taken from the NICT JLE Corpus shows that a student of Level 7 produced the following utterance: “In my hometown, *I mean* I don’t have a hometown right now since my parents moved to another town.” The student correctly uses the term *I mean* as a conversational strategy to clarify meaning.

According to Figure 2, *I mean* and *I guess* were especially underused by novice and lower intermediate learners of Level 1 to 5, compared to upper intermediate and advanced learners. The frequency of *I mean* showed a sudden increase at Level 6. On the other hand, the use of *I guess* suddenly increased at Level 8 while the frequency of *I mean* in Level 9 dropped from 90 to 60, which may suggest that the degree of self-correcting by advanced learners decreases as they improved their proficiency with increased vocabulary.

Figure 3 shows the frequency of strategies whose function is to sound more direct, in contrast to the strategies that soften comments. In the analysis just was excluded from the “softening” groups as it also has the function of making the utterance stronger. According to
Figure 2. Distribution of the use of *I guess* and *I mean* in the NICT JLE Corpus.

Figure 3. Distribution of direct and softening strategies in the NICT JLE Corpus.

In my analysis, there was an increase in the use of strategies regarding softening comments and when sounding more direct as student proficiency levels improved. Novice and lower intermediate learners tended to use softening comment strategies more frequently than direct
Miura, “L2 Spoken Corpora”

Figure 4. Distribution of the use of really, just, maybe, actually and kind of in the NICT JLE Corpus.

As shown in Table 2, the Touchstone Series introduces nine expressions for “sounding more direct” (of course, absolutely, definitely, really, actually, certainly, honestly, in fact, to be honest), and eight for “softening comments” (I guess, I think, probably, maybe, sort of, kind of, a little (bit), just). Except for the following five expressions really, actually, maybe, kind of and just, the other nine expressions for “sounding direct” and the remaining eight expressions used for “softening comments” were not analyzed for this study due to their infrequent use in the NICT JLE Corpus. Figure 4 presents the use of these five frequently used phrases, and clearly shows an increase specifically from Level 5 onwards. The highest increase occurs with the two phrases really and just, respectively. There is also a sharp increase for both phrases between Levels 6 and 8, which may either indicate overuse of the terms or an increased level of fluency. On the other hand, there was a decrease in the frequency of the phrase actually,
kind of and maybe as the proficiency levels increased.

Finally, regarding *like* and so, Japanese learners showed completely different tendencies from how they are actually introduced in the **Touchstone Series**. In Table 3, conversational analysis of dialogues extracted from Book 4 reveals six different functions of *like* and the percent of how each function is used by native speakers in the far right column.

Table 3

</tbody>
</table>

Figure 5 presents the distribution of the use of *like* among Japanese learners (see Appendix A for sample data taken from the NICT JLE Corpus). According to the results, *like* used as a verb was most frequent among Japanese learners, peaking at 500 tokens at Level 9, compared to native speakers who used *like* as a verb at only 17% (see table 3). There is quite a discrepancy between the two groups which becomes evident due to the data revealed from corpora studies.
Miura, “L2 Spoken Corpora”

Figure 6 presents the distribution of the use of so among Japanese learners (see Appendix B for sample data taken from the NICT JLE Corpus). There is a sharp increase in frequency between Level 1 and
Figure 6. Distribution of the use of so in the NICT JLE Corpus.

Figure 7. Distribution of the use of the items following after so in the NICT JLE Corpus.

Level 5 followed by a steady decline. The highest frequency at Level 5 suggests the overuse by lower intermediate learners, as compared to upper intermediate and advanced learners.

The unexpected finding with the high frequency counts in the level of lower intermediate learners led to further analysis on the
different contexts in which so is used. Particularly, the linguistic item following so was measured. Figure 7 shows that “I”, “Filler”, “Self-Correction”, “Comma” (which may indicate a certain length of pause), and “Repetition” are the top five items following so.

Discussion

First, an interesting result generated from the data was that frequency counts of the strategies such as I mean, actually, kind of and maybe were comparatively higher in the level of intermediate learners than that of upper intermediate and advanced learners. Intermediate learners possibly overused these words as fillers because of their lack of vocabulary and productive skills. Based on observations of my learners, the overuse of these strategies interferes with their conversational fluency. From a pedagogical perspective, students, specifically intermediate learners, should be made aware that the overuse of the term may hinder communication.

Secondly, the analysis of direct and softening strategies suggests that novice and lower intermediate learners show higher frequency of using “softening comments” than “sounding more direct”. This may be due to their L1 background, where the Japanese language tends to be less direct. However, Kaneko’s (2004) research into the development of speech acts in the NICT JLE Corpus revealed that intermediate learners were the most direct when making requests, which is contrary to the data collected for this study.

Some studies utilize discourse completion tasks as a method of data collection. Cole and Anderson’s (2001) longitudinal study showed their students used language that indicated an increase in more indirect conversational strategies after a ten-month homestay. Takahashi’s (1996) study into the transferability of Japanese indirect request strategies to corresponding English request contexts suggested that the learners’ pragmatic competence was not native speaker like,
regardless of their L2 proficiency. However, the results of the previously mentioned studies have varied and are inclusive regarding direct and indirect conversational strategies. One reason for this might be due to the small number of participants in those studies.

Following that, the distribution of various usages of *like* indicates that Japanese students rarely used *like* other than as a verb. This may be because it is common that Japanese learners have been introduced only to the usage of *like* as a verb in their secondary and tertiary educations, compared to more abstract uses such as when *like* is used to approximate. Although the frequency slightly increases as the proficiency level goes up, there is still a wide gap between the more concrete or easier uses of *like* than what might be perceived as the more difficult uses of *like*. According to McCarthy et al. (2006b), the native speakers use of *like* as types 2, 5, and 6 (see table 3) are used “in very informal conversations only” (p. 81)

However, one overwhelming appeal of the *Touchstone Series* is that the dialogues and instructional points in the series are based on empirical data taken from native speakers’ corpus. The results in the corpus of Japanese learners suggest that they should produce *like* with more varieties, but language teachers may have to be careful regarding the use of *like* in appropriate contexts. Yet, the more informal uses of *like* based on native speakers’ corpora (see table 3 sections 2, 5, and 6) may not be readily taught by language instructors, as some teachers tend not to encourage their students to use overly colloquial, informal and redundant language in their communication.

Finally, an interesting finding with the frequency counts of *so* and the analyses of its context should be “I” is the only lexical form, and others are hesitations or mumbles in the interviews. Level 4 and 5 show the highest frequency of the non-word items, and the occurrence decreases as the proficiency level increases. Lower proficiency level learners tend to seize speaking after uttering *so*, which can be related to the results of overusing *I mean, actually, maybe and a kind of*. From
the data, instructors should focus on the variety of different functions of like and so presented in Touchstone Series regarding pedagogical practices. In summary, the concern regarding colloquial usages in pedagogy may be realized in terms of the stance against heavy reliance on native speakers’ corpora as claimed by Granger (2002). This might provide us with a sense of caution when placing the norm on native speakers as discussed earlier in the present study.

**Conclusion**

The results of this study show how learners of each acquisition stage in the NICT Corpus performed differently in terms of the language usage related to conversational strategies. One important discovery was that Japanese learners did not necessarily exhibit their productive skills as the way textbook authors interpreted the native speakers’ corpus, or the North American segment of Cambridge International Corpus (CIC), which the Touchstone Series was based on. Another finding was that intermediate learners tended to overuse particular words and phrases, compared to those who were at upper intermediate and advanced levels. Thus, throughout the analysis, the features overused by intermediate learners seemed to function as fillers when they stopped speaking in order to search for what to say next.

Finally, the shortcomings with this study should be mentioned. There are items which show relatively low frequency or no occurrences, for example, absolutely, definitely, honestly, in fact, and to be honest as well as Did you? The last example, Did you? functions as an echo question to keep the conversation going (McCarthy et al. 2006a). Their absence or extremely low frequency from the NICT JLE Corpus may be due to the settings of the interviews, where students complete the assigned tasks so that they are assessed in terms of their oral proficiency. The SST interview, which the NICT JLE Corpus is based on, actually has five stages: (1) answering warm-up questions, (2) describing a single
picture, (3) having a role-play with the interlocutor, (4) narrating picture sequences, and (5) answering “wind-down questions.” Therefore, the whole corpus can be divided into subcorpora depending on the stages. However, the present study does not go into a deeper analyses focusing on each stage and task of the SST. The warm-up or wind-down, and role-play stages may be the best situations to explore the language of conversational strategies where a student and the interlocutor interact equally, while in the other stages the interlocutor produces utterances only to encourage a student to speak out.

In conclusion, although the Touchstone Series, with its corpus-informed syllabi, is carefully designed to meet the needs of learners at different developmental levels, the research into the NICT JLE Corpus suggests that language teachers still need to accommodate the syllabi, target language, and activities based on their own students’ needs. The study supports conclusions made by McCarthy (2004), McEnery et al. (2006), and O’Keefe et al. (2007) regarding corpora and syllabus design, specifically when McCarthy (2004) himself noted “corpus data alone does not dictate an instructional syllabus” (p.15).

The results of the analyses also reinforces the notion that corpus-informed language pedagogy should not solely be based on native speakers’ corpora, but should apply the extensive analyses of learner corpora as well. The application of learner corpora may even bridge the gap of claims made between corpus-based educationalists and their critics such as Cook (1998) and Widdowson (2000).

Acknowledgement

I would like to thank Dr. Yukio Tono at Tokyo University of Foreign Studies for access to the NICT JLE Corpus and his thoughtful comments on this research.
